### ABSTRACT

This study aimed to provide the first floristic checklist from Sorkhabad Protected Area in Zanjan Province, Northwest Iran. This area is one of the large protected areas in the Irano-Anatolian global biodiversity hotspot. This study was conducted based on the extensive field surveys during the growing season from 2019 to 2021. Our results documented 523 taxa of vascular plants belonging to 290 genera and 70 families. The most prominent families are Asteraceae (44 genera, 66 species), Brassicaceae (24 genera, 36 species), Poaceae (21 genera, 38 species) and Fabaceae (17 genera, 44 species). The richest genera are *Astragalus* L. (19 species), *Bromus* L., *Papaver* L., *Salvia* L. and *Silene* L. (each with 7 species), *Allium* L., *Centaurea* L., and *Glaucium* Mill. (each with 6 species). Hemicryptophytes (218 taxa, 42%) are the most dominant life form followed by therophytes (162 taxa, 31%), and Irano-Turanian elements (296 taxa, 57%) are the most common plants. Current results provide baseline data for future studies, such as conservation, and phytogeography.

**Keywords:** Floristic diversity, Qezel Ozan River, Irano-Anatolian, Qaflankoh Mountains, Zanjanrood River.

**Article type:** Research Article.

### INTRODUCTION

Protected areas are key strategies for conserving nature and halting the loss of biodiversity (Geldmann *et al.* 2019) and represent ecosystems valuable for the conservation of populations of native species and their habitats (Esina & Khapugin 2022). These areas are considered the primary defenses against biodiversity loss, provided they are well-maintained and managed (Heywood 2019). According to the latest Protected Planet Report, by 2020, at least 17% of terrestrial and inland waters will be conserved through protected areas. In Iran, 309 regions (10.36% of the country's total area) are under conservation management, including 32 national parks, 53 wildlife refuges, 40 national natural monuments, and 184 protected areas (Parchizadeh & Belant 2021). Two protected areas are located in Zanjan Province including Anguran and Sorkhabad. Sorkhabad Protected Area (SPA), which has been managed and protected since 1997, is situated northwest of Zanjan City. It is located in the Irano-Anatolian global biodiversity hotspot (Moghanloo *et al.* 2023) which covers an area of about 899,773 km<sup>2</sup>, and its considerable part is found in Northwestern Iran. It is a World Heritage Site known for its rich biodiversity, with about 6,000 plant species. Floristic inventory is a beneficial data source for biogeographical, ecological, and evolutionary surveys that provide suitable information for decision-making processes in biodiversity conservation and landscape projecting (Carta *et al.* 2018). By identifying the flora of different areas and comparing their diversity, the vegetation potential of the areas will be determined for more conservation programs (Saberamoli *et al.* 2021). Therefore, in Iran, as in other parts of the world, the floristic study in different regions has always been of focus of botanists (Mahmoodi *et al.* 2022). A few contributions to the floristic studies in adjacent protected areas,

including Arasbaran (Assadi 1988); Marakan (Ghahremaninejad & Nafisi 2011); Lissar (Ghahremaninejad *et al.* 2012) and Aq-Dagh (Molayi Shamasbi *et al.* 2021), have been published with an initial focus on the floristic composition of the protected areas and also on specific taxa. This study aims to provide the first checklist of the vascular plants in the SPA. Such floristic studies, in addition to investigating the plant diversity of a protected area, help to improve the knowledge of the flora in Zanjan Province. So far, several floristic studies have been conducted in different parts of Zanjan Province. The most important of which include: “Final report of a research project of collection and identification of plants of Zanjan Province and establishment of herbarium” (Musavi 2000), “An introduction of flora and phytogeographical elements of Khanchay Watershed in Tarome-olya of Zanjan” (Musavi 2004), “A study of the floristic composition, life form, and chorology of plants in three areas of Abhar County, southeast of Zanjan Province” (Vafadar *et al.* 2017) and, “Diversity of vascular plants in Damirli Mountains, Zanjan Province, NW of Iran” (Mahmoodi *et al.* 2022). The results of these studies indicate the great plant diversity and species richness in this province. Another study entitled “Diversity and distribution of endemic & threatened plant species in the Sorkhabad Protected Area, Zanjan, NW Iran, and identification of the biodiversity hotspots in the area” (Moghanloo *et al.* 2023) has also been conducted. This study, which is complementary to the present study, presents 141 plant species in this area, endemic to Iran or threatened species. In addition, the state of their population and their distribution in the western and eastern halves of the SPA have been comprehensively investigated.

## MATERIALS AND METHODS

### The study area

#### Geography and climate

Sorkhabad Protected Area (SPA), with a 122,618 ha situated between the geographical coordinates 36°44' to 37°08' N and 48°04' to 48°46' E. This area is located in the two counties, i.e., Zanjan and Tarom in Zanjan Province. There are many villages in this area. The boundary of SPA is determined between the two valleys of the Qezel Ozan River and Zanjanrood River. Fig. 1 illustrates SPA location in Zanjan Province, Iran. Based on geomorphological and field surveys, SPA mainly includes mountainous areas, Mahori hills, and plains. Most villages are located on Mahori hill and plains between mountain ranges. Regarding tectonics, most of the heights of the area are in the continuity of the Alborz Mountain range and include part of the Qaflankoh Mountains range. It is separated from Talesh Mountains by the Qezel Ozan River valley. The mountains of this area are mainly composed of volcanic rocks that have undergone tectonic changes. The elevation varies from 400 to 3000 meters above sea level (m.a.s.l.). Most of the area is located in the 1000 to 2200 m.a.s.l. The soil of the area often has a deep, loamy texture with 18% granular gravel and medium strength. The rate of permeability and erosion of soil is average; they do not have a limiting layer and have organic matter in the amount of 0.85%-1%. The climate of the area is the result of meteorological phenomena and is influenced by topographical factors, altitude, and the extent of plain lands. In the west, northwest, and south of the region, a cold semi-arid climate prevails; in the northeastern region, a cold semi-humid climate prevails. The cold and semi-humid climate of the northeastern region has a Caspian origin due to its border with Guilan Province and the effects of the humidity of the Caspian region and a part of the central and western Alborz highlands. The dominant climate type is the cold semi-arid region, which covers over 70% of the area.

### Vegetation

The vegetation and habitats of the studied area is very diverse because of the vastness of the area and variety of topography and climate. In the western half, the area begins with mountainous steppe habitats with the distribution of plants such as *Rosa persica* Michaut ex Juss., *Eremopyrum bonaepartis* (Spreng.) Nevski, *Alyssum dasycarpum* Stephan ex Willd., *Senecio glaucus* L., *Geranium kotschyii* Boiss., *Eremurus kopet-daghensis* Karrer, and the scattered shrubs of *Tamarix ramosissima* Ledeb. and *Salix acmophylla* Boiss. around the Zanjanrood River, which continues to the plains in the center of the area and in the surrounding residential zones, seen as ruderal or segetal habitats. By advancing towards the heights of Qaflankoh Mountains, we can see torn cushion steppe habitats with plants such as *Acantholimon asphodelinum* Mobayen, *Astragalus microcephalus* Willd. and in humid regions, scattered shrubs of species of *Rosa* L. and *Prunus* L. and perennial grasses are distributed in most of the slopes. At altitudes above 2400 m.a.s.l., especially in the north of the area, there are the snow beds habitats with plants such as *Puschkinia scilloides* Adams. In the heights of Qaflankoh Mountains towards the east of the area, which is more humid and warmer, the habitats of tree and shrub with plants such as *Paliurus spina-christi* Mill., *Pistacia*

*atlantica* Desf., *Acer monspessulanum* L., *Punica granatum* L., *Cotoneaster* spp., *Rubus sanctus* Kuntze, *Ficus carica* L., *Crataegus* spp., *Juniperus excelsa* M.Bieb., are densely distributed, especially in deep valleys along the rivers. Between the heights of Qaflankoh Mountains and the Qezel Ozan River, we can see dense and diverse covers of vegetation with plants such as *Papaver* spp., *Calendula arvensis* L., *Cleome rupicola* Vicary, and *Gundelia tournefortii* L. Finally, along the bank of the Qezel Ozan River, which is the eastern border of the area, shrubs such as *Populus euphratica* Olivier, *Pistacia atlantica*, and *Punica granatum* grows more.

## Methods

The floristic research was carried out during the growing seasons from 2019 to 2021. A total of 32 field trips in 95 stations were performed for sampling. Plots with random distribution and approximate sizes of 100 to 200 m<sup>2</sup> were established in each station according to the possibility of access, and the specimens of vascular plant taxa were collected. The exact location and altitude were determined using GPS. Some stations were visited several times, most at least twice a year. In the southern and southwestern parts of the area, there was no possibility for sampling due to the airport, military zone, and a number of mines and factories. Taxa were identified according to the Flora of Iran (Assadi 1988\_2024), Flora Iranica (Rechinger *et al.* 1963\_2015), Flora of Turkey (Davis 1965\_1988), Flora of Iraq (Townsend *et al.* 1966\_1974) and monographs published after these floras (such as *Ornithogalum*, Bidarlord & Ghahremaninejad 2016; *Phleum*, El-Gazzar *et al.* 2016; *Bromus* *et al.* 2015; *Scorzonera*, Norouzi *et al.* 2016; Solanaceae, Eskandari & Shirzadian 2022). The taxa families were defined based on the latest phylogenetic classification changes, such as APG IV. Also, the scientific names of species and their authors were applied based on reliable sources such as The Plant List ([theplantlist.org](http://theplantlist.org)) and Plants of the World Online, POWO ([powo.science.kew.org](http://powo.science.kew.org)). The chorology of species is based on Zohary (1973), Takhtajan (1986), White & Leonard (1999), and Flora of Iran (Assadi *et al.* 1988\_2024). Life form was categorized according to Raunkiaer (1934) as follows: Ch (Chamaephyte), Ge (Geophyte), He (Hemicryptophyte), Ph (Phanerophyte), and Th (Therophyte). All specimens were housed in the herbarium of Kharazmi University (T), Tehran, Iran.

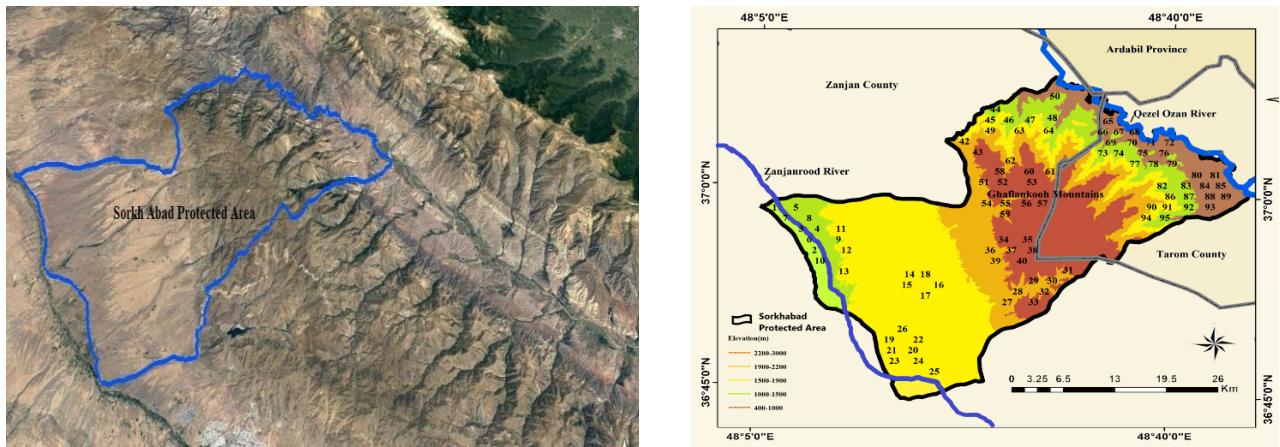

## RESULTS

### Floristic composition

A total of 523 taxa of vascular plants (including 499 species, 16 subspecies, and seven varieties) belonging to 290 genera within 70 families were collected and determined from SPA. Due to the presence of an airport and many residential regions, mines, gardens, and private agricultural lands, sampling was only allowed in a few places, and the natural vegetation of the regions was destroyed. Table 1 shows the checklist of vascular plants of SPA, and Figs. 2-9 are related to some of these taxa. In total, the vascular flora checklist of the SPA included 83.2% eudicots, 15.1% monocots, 0.9% gymnosperms, and 0.8% ferns. Regarding families, three and two families were ferns and gymnosperms, respectively. Angiosperms belonged to 65 families, with 11 monocots and 54 eudicots (Table 2).

### Life forms, elevational distribution, and phytogeography

Regarding the life form spectrum in this area, the majority of plant species (217 taxa, 42%) were adapted to cold semi-arid conditions as hemicryptophytes, followed by therophytes (161 taxa, 31%), geophytes (71 taxa, 14%), chamaephytes (38 taxa, 7%), and phanerophytes (35 taxa, 6%). Chamaephytes, such as suffruticose or thorny cushions, made relatively low contributions to the life form spectrum in this area. In relation to elevational distribution, 63% (329 number) of the species are distributed in mid-elevation zones (1000 to 1600 m and 1600 to 2200 m), which are the most zones in this area, 23% (120 number) in lowlands (400 to 1000 m) and 14% (73 number) in high elevations (2200 to 3000 m). Regarding phytogeography, about 57% (296 species) belonged to the Irano-Turanian floristic region, and 21% (109 species) were shared between Irano-Turanian and other regions. The rest of the species (117 species, 22%) are Pluriregional or Cosmopolitan, which are distributed in three or more phytogeographical regions (Fig. 10).

**Table 2.** List of angiosperms orders and families in SPA.

Monocots				Asparagales	Orchidaceae, Ixiliaceae, Iridaceae, Amaryllidaceae, Asparagaceae, Xanthorrhoeaceae
	Liliales	Colchicaceae, Liliaceae			
	Commelinids		Poales	Juncaceae, Cyperaceae, Poaceae	
Eudicots				Ranunculales	Papaveraceae, Berberidaceae, Ranunculaceae
				Proteales	Platanaceae
	Superrosids	Fabids	Saxifragales	Crassulaceae	
			Fabales	Fabaceae	
			Rosales	Rosaceae, Elaeagnaceae, Rhamnaceae, Moraceae, Urticaceae	
			Fagales	Juglandaceae	
			Malpighiales	Hypericaceae, Violaceae, Salicaceae, Euphorbiaceae, Linaceae	
		Rosids	Zygophyllales	Zygophyllaceae	
			Geraniales	Geraniaceae	
			Myrtales	Lythraceae, Onagraceae	
			Malvales	Malvaceae, Thymelaeaceae, cistaceae	
			Brassicales	Resedaceae, Capparaceae, Cleomaceae, Brassicaceae	
Core Eudicots	Superasterids	Asterids	Sapindales	Biebersteiniaceae, Anacardiaceae, Sapindaceae, Rutaceae	
			Vitales	Vitaceae	
			Santalales	Santalaceae	
			Caryophyllales	Tamaricaceae, Plumbaginaceae, Polygonaceae, Caryophyllaceae, Amaranthaceae, Portulacaceae	
			Ericales	Primulaceae	
		Campanulids	Asterales	Asteraceae	
			Apiales	Apiaceae	
			Dipsacales	Caprifoliaceae	
		Lamiids	Boraginales	Boraginaceae	
			Gentianales	Rubiaceae, Apocynaceae	
			Lamiales	Oleaceae, Plantaginaceae, Scrophulariaceae, Lamiaceae, Orobanchaceae	
			Solanales	Convulvolaceae, Solanaceae

## DISCUSSION

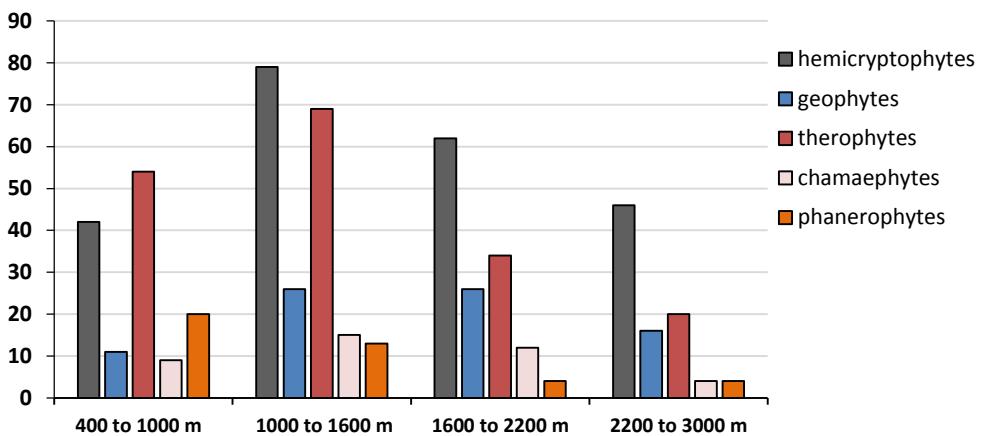

Among the orders and families presented in APG IV, 39 orders and 132 families have members in Iran (APG 2016). Sixty-five angiosperm families (49% of angiosperm families in Iran) and 26 angiosperm orders (67% of angiosperm orders in Iran) had representatives in SPA, reflecting the high angiosperm diversity in this area. The largest families of Iran were Fabaceae, Asteraceae, and Poaceae in terms of the number of species and Asteraceae, Poaceae, Apiaceae, and Fabaceae in terms of the number of genera (Rechinger *et al.* 1963-2015; Assadi *et al.* 1988-2024; Ghahremaninejad & Nejad Falatoury 2016; Bidarlord & Ghahremaninejad 2022). In SPA, eight families, including Asteraceae (13%) Fabaceae (8%), Poaceae (7%), Brassicaceae (about 7%), Lamiaceae (6%), Boraginaceae and Apiaceae (each including 5%), and Caryophyllaceae (4%) were the largest families in terms of the number of species (Fig. 11). These families account for 55% of the plant species in this area. Each of the other families had less than 20 species. About one-third of all the families were represented by only one species. Among the monotypic families of the area, Portulacaceae, Platanaceae, Ixiliriaceae, and Biebersteiniaceae also have only one species in Iran. In SPA, Asteraceae was the largest family regarding species and genera. Members of this family can spread easily, some of which have spines for protection against potential grazers; in addition, the family has a wide ecological tolerance (Archibald 1995). Another major group in the study area was Grasses. According to available information on the natural distribution of grasses, 50% of all species experience cold and freezing, suggesting that adaptations to these conditions are common and widespread in the Poaceae (Schubert *et al.* 2020). The members of this family were distributed in most parts of the study area and covered slopes of the heights. Also, perennial grasses such as *Alopecurus pratensis*, *Bromus tomentellus*, *Hordeum bulbosum*, *Lolium perenne*, and *Poa bulbosa* were found in the high and cold regions of the area. Due to *Astragalus* being included in the family Fabaceae, this family has attained first place in terms of species number in Iran (Ghahremaninejad *et al.* 2016; Ghahremaninejad & Joharchi 2020). Fabaceae is the second and fifth largest family in the SPA, regarding the number of species and genera, respectively. Consisting of 19 species, *Astragalus* was the largest genus in the SPA. Moreover, *Astragalus biserrula*, and *A. lilacinus* were new records from Zanjan Province. The other richest genera are *Bromus*, *Papaver*, *Salvia*, and *Silene* (each with 7 species) followed by *Allium*, *Centaurea*, and *Glaucium* (each with 6 species). The taxa of *Astragalus*, *Allium*, *Centaurea*, and *Silene* are typical members of the Irano-Turanian region. Iran is regarded as one of the important regions for *Salvia* diversity (Jamzad & Moein 2017), and in the SPA, the *Salvia* species are found in its different regions. *Papaver* comprises about 100 species, found primarily in temperate regions of the northern hemisphere (Goldblatt 1974), and in this area, most of its species were distributed in the eastern half. The dominance of hemicryptophytes and therophytes was in accordance with climatic conditions (Raunkjaer 1934) and indicating the cold mountain climate in most parts of the SPA. This result is similar to other studies conducted in mountain ecosystems such as Noroozi *et al.* 2010 and Aghajani *et al.* 2023. Except for the elevational zone of 400 to 1000 m.a.s.l., which was limited to the border of Qezel Ozan River in the eastern half, Hemicryptophytes were dominant in all of the elevational zones of SPA. In the zone of 400 to 1000 m.a.s.l., therophytes were common (Fig. 12b). The destruction of vegetation may cause the predominance of therophytes in this zone due to overgrazing. The increase of therophytes due to the damage

caused by anthropogenic activities and overgrazing is also observed in the results of floristic studies conducted in the Hyrcanian regions (Ghahremaninejad *et al.* 2011; Bazdid Vahdati *et al.* 2014; Ajamian *et al.* 2024). Comparing the two halves of the area in terms of the percentage of life forms showed that in the eastern half, the ratio of hemicryptophytes was almost twice that of therophytes, while in the western half, the ratio was almost equal, and both of them were dominant life forms in this half. The lowest life form in the eastern half was Chamaephytes and phanerophytes in the western half. Also, most of the samples of phanerophytes were collected from the eastern half. The ratio of geophytes and phanerophytes to other life forms was equal in both halves (Fig. 12 b).

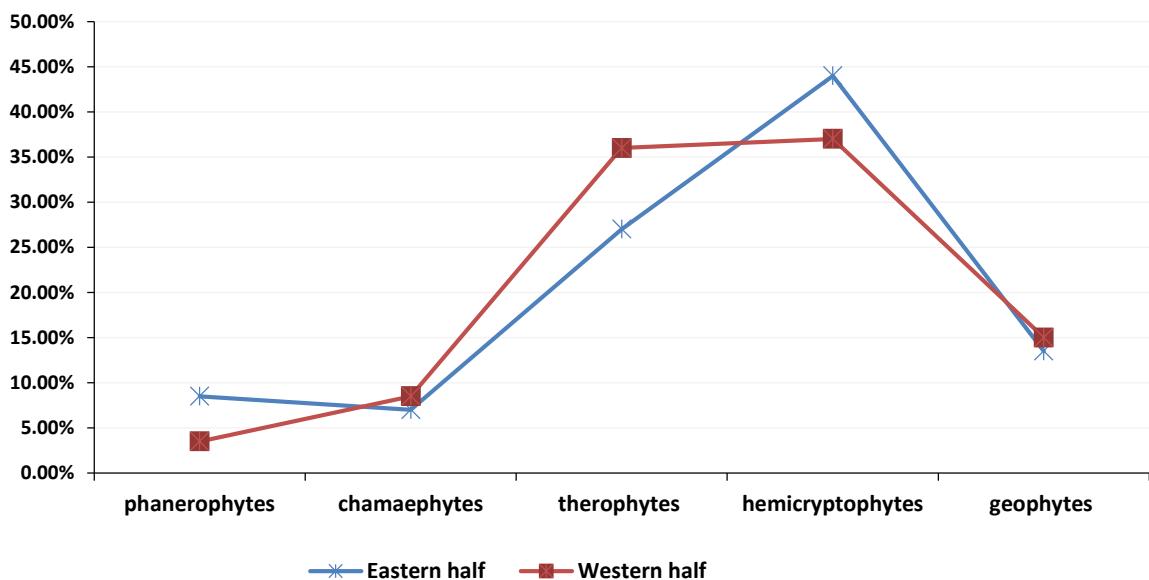

**Fig. 11.** The largest families in terms of diversity of vascular plant species and genera in SPA.

The predominance of plants of the Irano-Turanian region or regions shared with Irano-Turanian was quite expected considering the location of SPA in this phytogeographical region. The Irano-Turanian region shares with the Mediterranean basin numerous xerophilous plants (Bozkurt *et al.* 2022) and in this study, 12% of the plants were common between these two regions. In total 43% of the plants in the area were shared between 2 or more phytogeographical regions, which was due to the overlap of several regions or due to changes in weather conditions. By comparing the flora diversity of the study area with the adjacent protected areas, including Marakan, Lissar, and Aq-Dagh, similarities were found in dominant families and genera. Asteraceae and *Astragalus* were the largest family and genus, respectively. *Centaurea* and *Silene* were also among the large genera of these areas. In all areas, as expected, plants belonging to the Irano-Turanian region were dominant. In SPA, Aq-Dagh, and Lissar, hemicryptophytes were dominant that was followed by the therophytes, however in Marakan, therophytes were the dominant life form. In SPA, geophytes percentage were more than Chamaephytes, while in other areas, Chamaephytes were more than geophytes. Also, phanerophytes were the lowest life form in SPA and other regions. The low percentage of phanerophytes in SPA and adjacent areas showed that they were not adapted to the existing climate and edaphic situations.

## CONCLUSION

Sorkhabad Protected Area has a variety of habitats and vegetation due to its large size and variety of geographical location and topography and this shows the importance of this protected area in terms of vegetation diversity. The present study is the first floristic study of SPA that provides baseline data for future studies, like conservation, and phytogeography, especially in the regions of Qaflankoh Mountains, Qezel Ozan River, and Zanjanrood River.

## Conflicts of interest

None declared.

This study is a part of Leila Moghanloo's Ph.D. thesis at the University of Guilan (Rasht, Iran).
